Ultrasonic Mind Control

This FAQ examines claims about ultrasonic mind control, the science of ultrasound, proposed mechanisms of neurological influence, documented research, and the limitations of current technology. It distinguishes established scientific findings from speculation, misinformation, and unverified claims.

1. What is ultrasonic mind control?

Ultrasonic mind control is a term used to describe the alleged use of high-frequency sound waves to influence, manipulate, or control a person's thoughts, emotions, perceptions, or behaviour.

Ultrasound refers to sound waves with frequencies above the normal range of human hearing, generally above 20,000 hertz (20 kHz).

Although ultrasound has legitimate medical, industrial, and scientific applications, the claim that it can be used to remotely control someone's thoughts or behaviour is not established by scientific evidence.

2. What is ultrasound?

Ultrasound is mechanical sound energy that travels through a medium, such as air, water, or biological tissue.

w.w. ozian

It is used in several established fields:

- Medical imaging and diagnostic examinations.
- Physiotherapy and certain therapeutic procedures.
- High-intensity focused ultrasound (HIFU) treatments.
- Industrial testing and flaw detection.
- Scientific research and laboratory applications.

Ultrasound can interact with biological tissue, depending on its frequency, intensity, exposure duration and delivery method.

3. Can ultrasound affect the human brain?

Yes. Certain forms of ultrasound can interact with brain tissue.

Researchers have investigated transcranial focused ultrasound (tFUS) as a possible method of influencing neural activity.

Experimental studies have explored whether focused ultrasound can affect:

- Neuronal activity.
- Sensory processing.
- Motor responses.
- Brain connectivity.

- Specific neurological functions.

However, these findings do not demonstrate the ability to control a person's thoughts, implant beliefs, or remotely dictate behaviour.

4. What is transcranial focused ultrasound?

Transcranial focused ultrasound is an experimental and developing research technique that uses focused acoustic energy to reach targeted areas of the brain through the skull.

Researchers are investigating its potential applications in neuroscience and medicine, including neuromodulation and the study of neurological disorders.

It differs from ordinary audible sound and is not equivalent to a device that can transmit commands directly into someone's mind.

5. Can ultrasonic waves transmit thoughts into someone's brain?

There is no established scientific evidence that ultrasonic waves can transmit complex thoughts, sentences, memories, beliefs or instructions directly into a person's brain.

Ultrasound research involving neural stimulation is fundamentally different from transmitting meaningful mental content.

A person's ability to think, remember, interpret language and make decisions involves complex networks of neural activity that cannot currently be remotely programmed through ultrasound.

6. Can ultrasound cause someone to hear voices?

Ultrasound itself is generally outside the normal human hearing range. However, certain acoustic phenomena can produce audible effects.

It is important to distinguish between:

- Audible sound: Sound waves within the human hearing range.
- Ultrasound: Sound waves above the normal hearing range.
- Bone-conducted sound: Vibrations transmitted through bone and perceived through the auditory system.
- Auditory phenomena: Perceptions of sounds or voices that may occur for various neurological, psychological or environmental reasons.

There is no reliable evidence that ordinary airborne ultrasound can transmit intelligible conversations directly into someone's mind.

Ultrasonic Mind Control

7. What is the difference between ultrasonic mind control and auditory weapons?

These are different concepts.

Ultrasonic devices produce high-frequency acoustic energy. Auditory technologies may use other mechanisms to create unusual sound perceptions.

For example, the microwave auditory effect (sometimes called the Frey effect) involves the perception of sounds associated with pulsed radiofrequency energy. It is not an ultrasonic phenomenon.

Neither technology establishes the existence of a practical system for controlling human thoughts.

8. Can ultrasound influence emotions?

Researchers have investigated whether focused ultrasound can influence neural circuits associated with emotional processing.

However, research into neural stimulation does not establish that ultrasound can reliably create specific emotions, implant feelings, or dictate someone's emotional responses.

Emotional experiences involve multiple brain networks, physiological processes and environmental influences.

u.w. ozia

9. Can ultrasound implant memories?

There is no established scientific evidence that ultrasound can implant detailed memories into a person's brain.

Memory formation involves complex processes involving neuronal networks, synaptic plasticity and interactions between different brain regions.

Although ultrasound is being investigated for its effects on neural activity, this is not equivalent to creating or inserting memories.

10. Can ultrasonic technology influence behaviour?

Experimental neuromodulation research has investigated changes in specific neurological functions, including sensory and motor responses.

However, there is no established technology that uses remotely transmitted ultrasound to reliably dictate complex human behaviour, compel actions or override personal decision-making.

Ultrasonic Mind Control

11. Can ultrasonic waves penetrate walls?

Ultrasound can travel through certain materials, but its transmission depends on the material, frequency, intensity and other physical conditions.

High-frequency sound is generally attenuated relatively quickly in air. Walls and other solid materials can reflect, absorb or transmit acoustic energy to varying degrees.

The ability of ultrasound to travel through a material does not establish that it can influence the brain of someone on the other side.

12. Can someone be exposed to ultrasound without hearing it?

Yes. Ultrasound is generally inaudible to humans.

However, some devices also produce audible frequencies or other unwanted acoustic components.

The International Commission on Non-Ionizing Radiation Protection (ICNIRP) notes that airborne ultrasound exposure has been associated with non-specific complaints, including headaches, fatigue, dizziness and discomfort. The precise causes of these symptoms remain uncertain.

u.w.orian

13. What symptoms have been associated with airborne ultrasound exposure?

Reported complaints include:

- Headaches.
- Fatigue.
- Dizziness.
- Nausea.
- Discomfort.
- Auditory irritation.

These symptoms are non-specific and cannot independently establish exposure to ultrasound.

Other environmental, medical and psychological explanations should also be considered.

14. Is ultrasonic mind control an established military technology?

There is no publicly established scientific evidence demonstrating an operational ultrasonic system capable of remotely controlling human thoughts or behaviour.

Research into acoustic technologies, neurological stimulation and non-lethal systems does exist. However, the existence of research programmes or experimental equipment should not be interpreted as proof of mind-control capabilities.

Ultrasonic Mind Control

15. Is ultrasonic mind control the same as electromagnetic mind control?

No.

They involve different forms of physical energy.

Technology	Energy involved
Ultrasound	Mechanical acoustic waves
Radiofrequency technology	Electromagnetic radiation
Microwave technology	Electromagnetic radiation
Electrical brain stimulation	Electrical currents
Magnetic brain stimulation	Magnetic fields

These technologies have different physical properties, mechanisms and research applications.

16. Is ultrasonic mind control used in psychological abuse?

The term sometimes appears in discussions of alleged technological abuse, organised abuse and mind-control narratives.

www.oziat

However, allegations involving ultrasonic mind control should be distinguished from independently documented forms of psychological abuse, coercion, intimidation, sensory manipulation and trauma.

A person's account of distress or perceived technological interference deserves to be treated respectfully. Nevertheless, the specific mechanism should not be assumed without corroborating evidence.

17. Can ultrasonic mind control be detected?

Ultrasound can be measured using appropriately designed acoustic measurement equipment.

Detection requires consideration of:

- Frequency range.
- Acoustic pressure.
- Exposure duration.
- Measurement location.
- Background noise.
- Equipment calibration.

Ultrasonic Mind Control

A conventional audio recording or smartphone application cannot reliably establish the presence or absence of all ultrasonic frequencies.

18. Is ultrasonic mind control scientifically proven?

Scientific distinction
The following distinctions are important:

Claim	Scientific status
Ultrasound can interact with biological tissue	Established
Focused ultrasound can influence neural activity	Supported by experimental research
Ultrasound is being investigated for neurological treatment	Established
Ultrasound can transmit complex thoughts	Not established
Ultrasound can implant memories	Not established
Ultrasound can remotely control someone's behaviour	Not established
Ultrasound can reliably produce mind control	No supporting scientific evidence

u.w. ozian

19. What are the potential health risks of ultrasound exposure?

Potential effects depend on the intensity, frequency, duration and method of exposure.

High-intensity focused ultrasound can produce heating and tissue damage. Medical ultrasound therefore requires appropriate equipment, exposure controls and professional oversight.

Low-intensity transcranial ultrasound is also being studied for safety, and questions remain about long-term exposure and repeated treatments.

20. Where can people find reliable information about ultrasonic technology?

The following organisations and publications provide useful scientific information:

1. International Commission on Non-Ionizing Radiation Protection (ICNIRP) – Information about ultrasound exposure and safety. ICNIRP ultrasound information.
2. National Institutes of Health (NIH) – Biomedical and neurological research. PubMed research database.
3. Nature Reviews Methods Primers – Research on low-intensity focused ultrasound for human neuromodulation. Read the 2024 scientific review.

4. International Transcranial Ultrasonic Stimulation Safety and Standards Consortium (ITRUSST) – Research standards and safety considerations for transcranial ultrasound.
